

# An Introduction to Latent Order LOGistic (LOLOG) Network Models

*The Statnet Development Team*

*2018-03-21*

## Getting Started

This vignette is based on the vignette from the `ergm` package, and is designed to give a working introduction to LOLOG modeling.

This package will utilize the `statnet` suite of packages for data and network manipulation. To install these:

```
install.packages("statnet")
```

To install the latest version of the package from CRAN (not yet available):

```
install.packages("lolog")
```

To install the latest development version from github run the following (you'll need a sh shell and git):

```
git clone https://github.com/fellstat/lolog.git
sh lolog/mkdist
```

## Statistical Network Modeling: The `lolog` Command and `lolog` Object

Make sure the `lolog` package is attached:

```
library(lolog)
set.seed(1)
```

The `ergm` package contains several network data sets that you can use for practice examples.

```
suppressPackageStartupMessages(library(ergm))
#data(package='ergm') # tells us the datasets in our packages
data(florentine) # loads flomarriage and flobusiness data
flomarriage # Let's look at the flomarriage data
#> Network attributes:
#>   vertices = 16
#>   directed = FALSE
#>   hyper = FALSE
#>   loops = FALSE
#>   multiple = FALSE
#>   bipartite = FALSE
#>   total edges= 20
#>   missing edges= 0
#>   non-missing edges= 20
#>
#> Vertex attribute names:
#>   priorates totalties vertex.names wealth
#>
#> No edge attributes
plot(flomarriage) # Let's view the flomarriage network
```

Networks tend to evolve over time. This evolution can take the form of the addition or deletion of a tie from the network, or the addition or deletion of a vertex. LOLOGs are motivated by a growth process, where each edge variable is sequentially considered for edge creation, and edges are not deleted.

Remember a LOLOG represents the probability of a tie, given the network grown up to a timepoint as

$$\text{logit}(p(y_{s_t} = 1 | \eta, y^{t-1}, s_{\leq t})) = \theta \cdot c(y_{s_t} = 1 | y^{t-1}, s_{\leq t})$$

where  $s_{\leq t}$  is the growth order of the network up to time  $t$ ,  $y^{t-1}$  is the state of the graph at time  $t - 1$ .  $c(y_{s_t} | y^{t-1}, s_{\leq t})$  is a vector representing the change in graph statistics from time  $t - 1$  to  $t$  if an edge is present, and  $\theta$  is a vector of parameters.

## An Erdos-Renyi model

We begin with the simplest possible model, the Bernoulli or Erdos-Renyi model, which contains only an edge term.

```
flomodel.01 <- lollog(flomarriage~edges) # fit model
#> Initializing using variational fit
#>
#> Model is dyad independent. Replications are redundant. Setting nReplicates <- 1L.
#> Model is dyad independent. Returning maximum likelihood estimate.
flomodel.01
#> MLE Coefficients:
#> edges
#> -1.609438

summary(flomodel.01) # look in more depth
#> observed_statistics theta se pvalue
#> edges 20 -1.609438 0.2449451 0
```

How to interpret this model? The log-odds of any tie occurring is:

$$= -1.609 \times \text{change in the number of ties} = -1.609 \times 1$$

for all ties, since the addition of any tie to the network changes the number of ties by 1!

Corresponding probability is:

$$\exp(-1.609)/(1 + \exp(-1.609)) = 0.1667$$

which is what you would expect, since there are 20/120 ties.

## A Triangle Model

Let's add a term often thought to be a measure of clustering: the number of completed triangles.

```
flomodel.02 <- lolog(flomarriage~edges()+triangles(), verbose=FALSE)
summary(flomodel.02)
#>      observed_statistics      theta      se pvalue
#> edges                20 -1.6350235 0.2610002 0.0000
#> triangles              3  0.2007203 0.7161925 0.7793
```

```
coef1 = flomodel.02$theta[1]
coef2 = flomodel.02$theta[2]
logodds = coef1 + c(0,1,2) * coef2
expit = function(x) 1/(1+exp(-x))
ps = expit(logodds)
coef1 = round(coef1, 3)
coef2 = round(coef2, 3)
logodds = round(logodds, 3)
ps = round(ps, 3)
```

Again, how to interpret coefficients?

Conditional log-odds of two actors forming a tie is:

$$-1.635 \times \text{change in the number of ties} + 0.201 \times \text{change in number of triangles}$$

- if the tie will not add any triangles to the network, its log-odds is:  $-1.635$ .
- if it will add one triangle to the network, its log-odds is:  $-1.635 + 0.201 = -1.434$
- if it will add two triangles to the network, its log-odds is:  $-1.635 + 0.201 \times 2 = -1.234$
- the corresponding probabilities are 0.163, 0.192, and 0.226.

Let's take a closer look at the ergm object itself:

```
class(flomodel.02) # this has the class ergm
#> [1] "lologGmm" "lolog"      "list"

names(flomodel.02) # let's look straight at the ERGM obj.
#> [1] "method"      "theta"        "stats"
#> [4] "estats"      "auxStats"     "obsStats"
#> [7] "net"         "grad"         "vcov"
#> [10] "likelihoodModel"
```

```
flomodel.02$theta
#>      edges triangles
#> -1.6350235  0.2007203
flomodel.02$formula
#> NULL
wealth <- flomarriage %v% 'wealth' # the %v% extracts vertex
wealth # attributes from a network
#> [1] 10 36 55 44 20 32 8 42 103 48 49 3 27 10 146 48
plot(flomarriage, vertex.cex=wealth/25) # network plot with vertex size
```

```
# proportional to wealth
```

## The Effect of Wealth

We can test whether edge probabilities are a function of wealth:

```
flomodel.03 <- lollog(flomarriage~edges+nodeCov('wealth'))
#> Initializing using variational fit
#>
#> Model is dyad independent. Replications are redundant. Setting nReplicates <- 1L.
#> Model is dyad independent. Returning maximum likelihood estimate.
summary(flomodel.03)
#>               observed_statistics          theta          se pvalue
#> edges                20 -2.59492903 0.536051763 0.0000
#> nodecov.wealth       2168  0.01054591 0.004674236 0.0241
```

Yes, there is a significant positive wealth effect on the probability of a tie.

## Reciprocity

Let's try a model or two on:

Is there a statistically significant tendency for ties to be reciprocated ('mutuality')?

```
data(samplk)
ls() # directed data: Sampson's Monks
#> [1] "coef1"          "coef2"          "emptyNetwork"
#> [4] "expit"          "fauw.mesa.high" "fauwmodel.01"
#> [7] "fauwmodel.02"   "flobusiness"    "flomarriage"
#> [10] "flomodel.01"    "flomodel.02"    "flomodel.03"
#> [13] "flomodel.04"    "g"              "gdeg"
#> [16] "gesp"           "inlineLologPlugin" "logodds"
#> [19] "makeEmptyNetwork" "mesa"          "net"
#> [22] "nets"          "nw2"            "ps"
#> [25] "samplike"       "samplk1"        "samplk2"
#> [28] "samplk3"       "sampmodel.01"   "src"
#> [31] "wealth"
samplk3
```

```

#> Network attributes:
#> vertices = 18
#> directed = TRUE
#> hyper = FALSE
#> loops = FALSE
#> multiple = FALSE
#> bipartite = FALSE
#> total edges= 56
#> missing edges= 0
#> non-missing edges= 56
#>
#> Vertex attribute names:
#> cloisterville group vertex.names
#>
#> No edge attributes
plot(samplk3)

```

```

sampmodel.01 <- lolog(samplk3~edges+reciprocity, verbose=FALSE)
summary(sampmodel.01)
#> observed_statistics theta se pvalue
#> edges 56 -1.780017 0.1710626 0e+00
#> reciprocity 15 2.487496 0.6743379 2e-04

```

## Modeling Larger Networks

Let's try a larger network. First we will fit a dyad independent model.

```

data(faux.mesa.high)
mesa <- faux.mesa.high
mesa
#> Network attributes:
#> vertices = 205
#> directed = FALSE
#> hyper = FALSE
#> loops = FALSE
#> multiple = FALSE
#> bipartite = FALSE
#> total edges= 203
#> missing edges= 0

```

```
#>      non-missing edges= 203
#>
#> Vertex attribute names:
#>      Grade Race Sex
#>
#> No edge attributes
plot(mesa, vertex.col='Grade')
```

```
#legend('bottomleft',fill=7:12,legend=paste('Grade',7:12),cex=0.75)
mesa %v% "GradeCat" <- as.character(mesa %v% "Grade")
fauxmodel.01 <- lolog(mesa ~edges + nodeMatch('GradeCat') + nodeMatch('Race'))
#> Initializing using variational fit
#>
#> Model is dyad independent. Replications are redundant. Setting nReplicates <- 1L.
#> Model is dyad independent. Returning maximum likelihood estimate.
summary(fauxmodel.01)
```

|                       | observed_statistics | theta      | se        | pvalue |
|-----------------------|---------------------|------------|-----------|--------|
| #> edges              | 203                 | -6.2254111 | 0.1737005 | 0.0000 |
| #> nodematch.GradeCat | 163                 | 2.8278899  | 0.1773356 | 0.0000 |
| #> nodematch.Race     | 103                 | 0.4266748  | 0.1427599 | 0.0028 |

Now lets try adding in transitivity and 2-stars (a measure of degree spread)

```
# This may take a minute or two
fauxmodel.02 <- lolog(mesa ~edges + nodeMatch('GradeCat') + nodeMatch('Race') +
  triangles + star(2), verbose=FALSE)
summary(fauxmodel.02)
```

|                       | observed_statistics | theta       | se         | pvalue |
|-----------------------|---------------------|-------------|------------|--------|
| #> edges              | 203                 | -6.32253753 | 0.23009490 | 0.0000 |
| #> nodematch.GradeCat | 163                 | 2.59264481  | 0.19642150 | 0.0000 |
| #> nodematch.Race     | 103                 | 0.41817975  | 0.16839142 | 0.0130 |
| #> triangles          | 62                  | 3.07545054  | 0.75245219 | 0.0000 |
| #> star.2             | 659                 | 0.02291813  | 0.05504247 | 0.6771 |

We see strong evidence of additional transitivity, but little evidence that the degrees have higher spread than expected given the other terms. With LOLOG models, we avoid some of the degeneracy problems present in ERGM models. Let's try the same model in ergm

```
fauxmodel.01.ergm <- ergm(mesa ~ edges + nodematch('GradeCat') + nodematch('Race') +
                          triangles + kstar(2))
#> Starting maximum likelihood estimation via MCMLE:
#> Iteration 1 of at most 20:
#> Error in ergm.MCMLE(init, nw, model, initialfit = (initialfit <- NULL), : Number of edges in a simul
```

Of course it is highly recommended that you take great care in selecting terms for use with ergm for precisely the reason that many can lead to model degeneracy. A much better choice here for the ergm model would have been to use gwespc and gwdegree in place of triangles and 2-stars.

## Model Terms Available for LOLOG Estimation and Simulation

Model terms are the expressions (e.g. triangle) used to represent predictors on the right-hand side of equations used in: - calls to lolog (to estimate an ergm model) - calls to simulate (to simulate networks from an lolog model fit) - calls to calculateStatistics (to obtain measurements of network statistics on a dataset)

### Terms Provided with lolog

For a list of available terms that can be used to specify an ERGM, type:

```
help('lolog-terms')
```

### Coding New Terms

Full details on coding new terms is beyond the scope of this document. However, lolog provides facilities for extending the package to provide new terms. An example of this can be created via

```
lologPackageSkeleton()
```

and then at the command prompt, run

```
R CMD build LologExtension
R CMD INSTALL LologExtension_1.0.tar.gz
```

A new package will be installed implementing the minDegree (minimum degree) statistic.

Alternatively, C++ extensions can be added directly from R without the need of any package infrastructure via the inlining features of the Rcpp package. lolog provides an inline plugin for this feature. For details, see

```
help("inlineLologPlugin")
```

## Network Simulation and Computation

Network Statistics can be calculated using the calculateStatistics function

```
calculateStatistics(mesa ~ edges + triangles + degree(0:15))
#>      edges triangles degree.0 degree.1 degree.2 degree.3 degree.4
#>      203         62       57       51       30       28       18
#> degree.5 degree.6 degree.7 degree.8 degree.9 degree.10 degree.11
#>      10         2         4         1         2         1         0
#> degree.12 degree.13 degree.14 degree.15
#>      0         1         0         0
```

Simulating from a fit lolog object with

```
nets <- simulate(flomodel.03,nsim=10) #Generates a list of BinaryNet objects
plot(nets[[1]])
```

Voila. Of course, yours will look somewhat different. Note that the objects created are BinaryNet objects unless the convert parameter is set to TRUE, in which case they are network objects.

## Working with BinaryNet objects

BinaryNets are network data structures native to the lolog package. They are special in a couple ways. First, they have a sparse representation of missingness, such that a directed network where halve of the nodes have been egocentrically sampled takes the same amount of space as a simple fully observed network. Secondly, they may be passed up and down easily from R to C++ and visa versa. Finally, they are extensible on the C++ level, so that their implementation may be replaced. For example, it might be useful to put in a file backed storage system for large problems.

BinaryNets can be coerced to and from network objects.

```
data(sampson)

#coersion
net <- as.BinaryNet(samplike)
nw2 <- as.network(net)
print(nw2)
#> Network attributes:
#>   vertices = 18
#>   directed = TRUE
#>   hyper = FALSE
#>   loops = FALSE
#>   multiple = FALSE
#>   bipartite = FALSE
#>   total edges= 88
#>     missing edges= 0
#>     non-missing edges= 88
#>
#> Vertex attribute names:
#>   cloisterville group vertex.names
#>
#> No edge attributes
```

```

#dyad Extraction

#See available methods
#print(DirectedNet)
#print(UndirectedNet)

```

All user facing functions in the lolog package accept BinaryNets as arguments, and will convert network objects to BinaryNets automatically.

## Order Dependent Terms

LOLOG allows for network statistics that depend not just on the network, but also the (unobserved) order in which dyads were ‘added’ to the network. One model of this class is the Babarasi-Albert preferential attachment model, which is closely approximated by a lolog model with an edges and preferentialAttachment term.

For each order dependent statistic, one or more order independent statistics must be specified as moment matching targets. In this case, we will use two-star

```
flomodel.04 <- lolog(flomarriage ~ edges() + preferentialAttachment(),
                    flomarriage ~ star(2), verbose=FALSE)
summary(flomodel.04)
```

| #>                        | observed_statistics | theta      | se       | pvalue |
|---------------------------|---------------------|------------|----------|--------|
| #> edges                  | 20                  | -1.6961715 | 2.558991 | 0.5074 |
| #> preferentialAttachment | NA                  | -0.0354842 | 1.037945 | 0.9727 |

## Examining the Quality of Model Fit - GOF

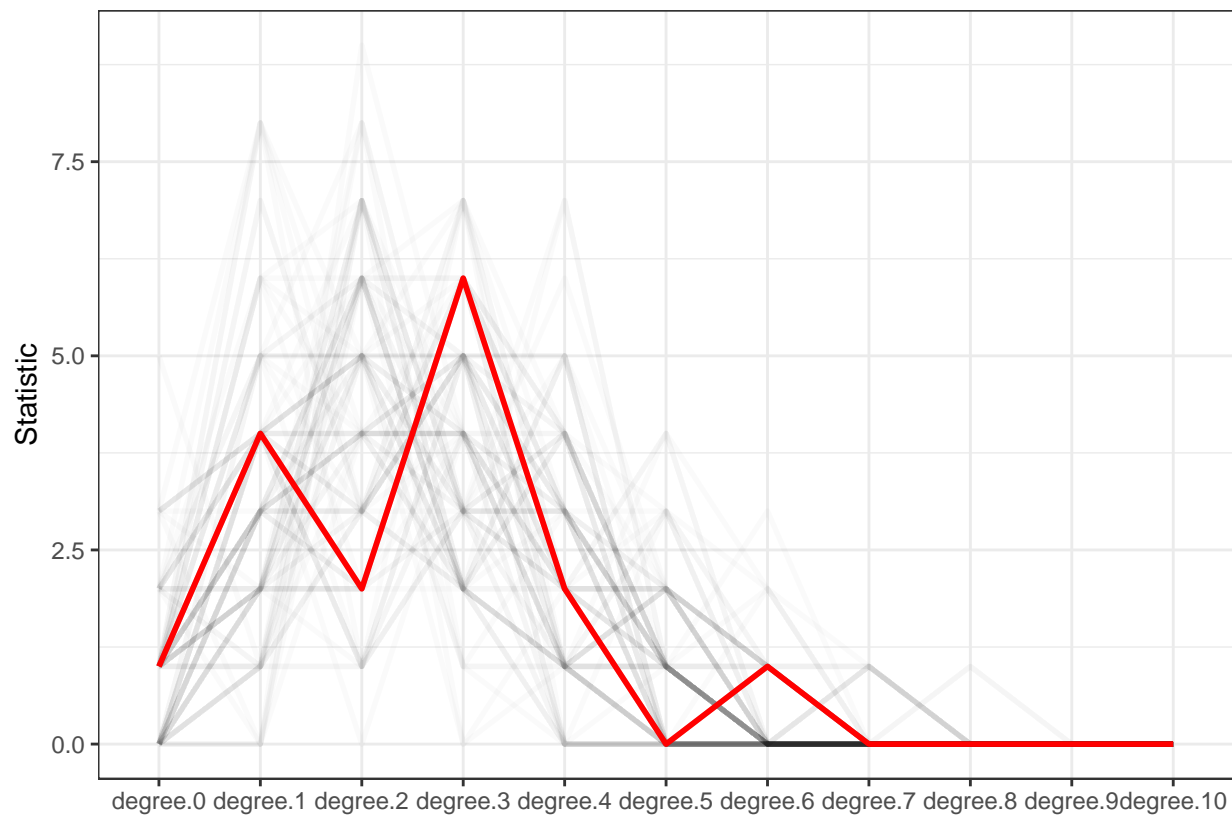

LOLOGs are generative models - that is, they represent the process that governs tie formation at a local level. These local processes in turn aggregate up to produce characteristic global network properties, even though these global properties are not explicit terms in the model. One test of whether a model “fits the data” is therefore how well it reproduces these global properties. We do this by choosing a network statistic that is not in the model, and comparing the value of this statistic observed in the original network to the distribution of values we get in simulated networks from our model.

We begin by comparing the degree structure of simulated nets compared to the observed (red)

```
gdeg <- gofit(flomodel.03, flomarriage ~ degree(0:10))
gdeg
```

| #>           | obs | min | mean | max | pvalue    |
|--------------|-----|-----|------|-----|-----------|
| #> degree.0  | 1   | 0   | 1.06 | 5   | 0.9523094 |
| #> degree.1  | 4   | 0   | 3.20 | 8   | 0.6687044 |
| #> degree.2  | 2   | 0   | 4.20 | 9   | 0.2664468 |
| #> degree.3  | 6   | 0   | 3.83 | 7   | 0.2033616 |
| #> degree.4  | 2   | 0   | 2.30 | 7   | 0.8528553 |
| #> degree.5  | 0   | 0   | 0.98 | 4   | 0.3524339 |
| #> degree.6  | 1   | 0   | 0.32 | 3   | 0.2578741 |
| #> degree.7  | 0   | 0   | 0.09 | 1   | 0.7543497 |
| #> degree.8  | 0   | 0   | 0.02 | 1   | 0.8869686 |
| #> degree.9  | 0   | 0   | 0.00 | 0   | NA        |
| #> degree.10 | 0   | 0   | 0.00 | 0   | NA        |

```
plot(gdeg)
```

Next we can look at the edgewise shared partner distribution in simulated networks compared with the observed distribution(red)

```
gesp <- gofit(flmodel.03, flomarriage ~ esp(0:5))
gesp
#>      obs min  mean max  pvalue
#> esp.0  12   3 13.71 21 0.6484374
#> esp.1   7   0  5.48 17 0.6696853
#> esp.2   1   0  1.00  7 1.0000000
#> esp.3   0   0  0.09  2 0.7975781
#> esp.4   0   0  0.02  1 0.8869686
#> esp.5   0   0  0.00  0      NA
plot(gesp)
```
